The X-pen is an increasingly popular hand-held, disposable electromyographic (EMG) transducer designed to eliminate need for sterile wrap, although little information is available on its potential hazards. The purpose of this study was to assess the effect of the X-pen on the ulnar nerve and to examine the stability of the X-pen signal. The ulnar nerve was exposed bilaterally in three 10-week-old sheep. The right ulnar nerve was stimulated with a neurostimulator and its compound muscle action potential (CMAP) was recorded with the X-pen. The left ulnar nerve was stimulated with the neurostimulator and its CMAP was recorded with a bipolar EMG recording electrode inserted through the sheath of the X-pen. The X-pen signal was then compared with the CMAP signal for each nerve. The effects of repositioning and compression on the X-pen signal were examined. Both nerves had normal responses to stimulation with the neurostimulator. The CMAP from the right ulnar nerve was easily identified when recorded with the X-pen. The CMAP from the left ulnar nerve was absent on stimulation of this nerve with the neurostimulator but was clearly visible with the X-pen. Repositioning of the X-pen for one to two minutes or compression of the X-pen for 10 to 15 seconds had no effect on the CMAP from the left ulnar nerve. However, compression of the X-pen for 40 to 60 seconds markedly reduced the CMAP from the left ulnar nerve. In contrast, repositioning of the X-pen for one to two minutes had no effect on the CMAP from the right ulnar nerve. Repositioning of the X-pen for 1 to 2 minutes or application of compression to the X-pen did not appear to adversely affect the signal.Alfred C. Kinney 82157476af
